

EXAMS

Answer to Task 1

a)

$$Y = X\theta + E$$

$$Y = [Y(1), Y(2), \dots, Y(N)]$$

$$X = \begin{bmatrix} 1 & 0 & 0 & u(1) \\ 1 & 0 & x(1) & u(2) \\ 1 & x(2) & 1 & u(3) \\ \vdots & \vdots & \vdots & \vdots \\ 1 & x(N-1) & x(N-2) & u(N) \end{bmatrix}$$

$$\theta = \begin{bmatrix} a_1 \\ b_1 \\ c_1 \end{bmatrix}$$

$$E = \begin{bmatrix} e(1) \\ e(2) \\ \vdots \\ e(N) \end{bmatrix}$$

Figure 1: Task1

b) U and E should be independent. If E is white noise, then as n approaches positive infinity, it becomes bias-free.

$$P_N = E(\hat{\theta}_N - \theta_0)(\hat{\theta}_N - \theta_0)^T \approx \frac{1}{N} \lambda R^{-1}$$

$$P = X^T X = E \begin{bmatrix} Y(k-1) \\ Y(k-2) \\ u(k) \end{bmatrix} \begin{bmatrix} Y(k-1) & Y(k-2) & u(k) \end{bmatrix} = \begin{bmatrix} R_{Y(0)} & R_{Y(1)} & 0 \\ R_{Y(1)} & R_{Y(2)} & 0 \\ 0 & 0 & R_{u(0)} \end{bmatrix}$$

$u \sim (0, 1)$ and u & e are independent.

$e \sim (0, 1)$

$$P_{Y(0)} = E(a_1 Y(t-1) + a_2 Y(t-2) + b u(t) + v(t))^2$$

$$P_{Y(1)} = E(Y(t) Y(t-1)) = E(a_1 Y(t-1)^2 + a_2 Y(t-1) Y(t-2) + b u(t) Y(t-1) + v(t) Y(t-1))$$

Figure 2: Task1 b

Answer to Task 2: Supervised Learning

a) I noticed that in this code, there is no regularization applied to the data and no filtering for the data.

First, I detected outliers and scaled the dataset, implementing normalization. Next, I selected relevant features through a heatmap. Finally, I used a random forest for classification.

b)

```
1 from sklearn.ensemble import RandomForestClassifier
2 rf = RandomForestClassifier(n_estimators=50, oob_score=True, random_state=1234)
3 rf.fit(x_train, y_train)
4 yp = rf.predict(x_test)
5 acc = metrics.accuracy_score(y_test, yp) # classifier accuracy
6 rmse = rmse(yp, y_test.values) # rms error
7 # score = rf.score(x_train, y_train)
8 print("err ", rmse)
```

However, the results are not very satisfactory. The RMS error for k-NN is 2.3, and when switched

to a random forest, the RMS error becomes 2.5.

Answer to Task 3: System Identification

Firstly, I observed the data and found that it was consistently zero between 1900 and 2100, which is clearly abnormal. Therefore, I removed this portion of the data. Secondly, I tested the parameters of the ARX model and selected [15 15 1]. Then, I compared it with the OE model, and the OE model's performance was slightly better than ARX. From the Bode plot and residual plot, I obtained satisfactory results

```
1 %%
2 y(1901:2100) = [];
3 u(1901:2100) = [];
4 N = length(y);
5
6
7 %%
8 N = [6 6 1];
9 O = oe(z,N);
10 compare(ztest,O,M,Inf)
11 % resid(ztest,O)
12 present(O)
```

Figure 3: Task3 plot

Compare OE and ARX.

Figure 6: Task3 OE response

Answer to Task 4: Causal Inference

a) 1 b) 2 c) 1

d) Because when $Y = S + W$, although it blocks the path $S \rightarrow W \rightarrow M$, there is still an unblocked backdoor path: $S \rightarrow W \rightarrow D \rightarrow M$, which affects the coefficient of S . To resolve this issue, it is necessary to choose $Y = S + W + D$. The results I obtained after assigning a value to C in Colab also confirmed this hypothesis.

e)

```
1 c1 = 1
2 c2 = 2
3 c3 = 3
4 c4 = 4
5 c5 = 5
6
7 results1 = smf.ols('Y ~ S + W + D', data=dat1).fit()
8 print(results1.summary())
```

It can be observed that the coefficient of S is approximately equal to $C1$.

Notes:						
[1] Standard Errors assume that the covariance matrix of the errors is correctly specified.						

Figure 7: Task4 result

Answer to Task 5: Model Reduction

a) By changing the sensor position and testing the Bode plot, we can observe that when the position is less than 0.75, the accuracy of the second-order system can be maintained at 0.1 rad/s. As the sensor position gets closer to the tail, the error gradually increases in the first 30 seconds. When the position is greater than 0.75, a higher-order system is required.

Figure 8: Task52

b) At 20% and 50% of the length of the rod, using a second-order system can maintain accuracy, but there is still some error in the first 30 seconds. For 80%, a third-order system is needed, and the error in the first 30 seconds has been significantly improved.

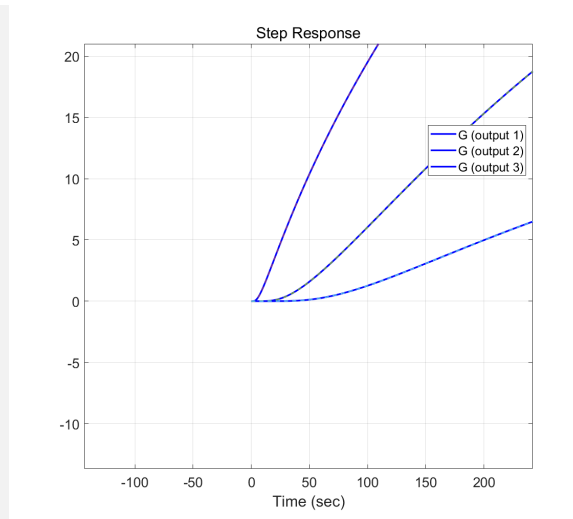

Figure 9: Task53

Answer to Task 6: System Identification Theory

$$\begin{aligned}
 x(t) &= a_1 x(t-1) + a_2 x(t-2) + b u(t) + e(t) \\
 \hat{\theta} &= \frac{1}{N} \sum_{k=1}^N \hat{\theta}(k) \\
 \text{Var}(x) &= E(x - \bar{x})^2 \quad \bar{x} = E(x) \\
 \text{Var}(ax) &= a^2 \text{Var}(x) \quad \text{Var}(Ax) = A \text{Var}(x) A^T \\
 E(Ax) &= A E(x) \\
 R &= E \begin{bmatrix} y(k-1) \\ y(k-2) \\ u(k) \end{bmatrix} \begin{bmatrix} y(k-1) & y(k-2) & u(k) \end{bmatrix} = \begin{bmatrix} R_{yy(1)} & R_{yy(12)} & 0 \\ R_{yy(12)} & R_{yy(2)} & 0 \\ 0 & 0 & R_{uu} \end{bmatrix} \\
 \text{Since } E(u(t)u(s)) &= E(e(t)e(s)) = E(u(t), u(s)) = 0 \quad (t \neq s) \\
 E(u(t)) &= E(e(t)) = 1 \quad \text{and } E(e(t)u(s)) = \rho, \quad | \rho | \leq 1 \\
 R_{yy(1)} &= E(a_1 y(t-1) + a_2 y(t-2) + b u(t) + v(t))^2 \quad R_{uu(0)} = 0 \\
 R_{yy(1)} &= E(a_1 y(t-1) + a_2 y(t-2) + b u(t) + \rho)^2 \quad R_{uu(0)} = \rho.
 \end{aligned}$$
